RESEARCH PROGRESS REPORT SUMMARY

Grant 02292: Broad-Range Detection of Canine Tick-Borne Disease and Improved Diagnostics Using Next-Generation Sequencing

Principal Investigator:	Pedro Diniz, DVM, PhD
Research Institution:	Western University of Health Sciences
Grant Amount:	$60,717.00

Start Date: 9/1/2016   **End Date:** 4/30/2018

Progress Report: Mid-Year 2

Report Due: 2/28/2018   **Report Received:** 3/2/2018

(The content of this report is not confidential and may be used in communications with your organization.)

Original Project Description:

Diagnostic tests based on the detection of DNA of infectious organisms from clinical samples have revolutionized veterinary medicine in the last decades. Currently, diagnostic panels for several tick-borne organisms are available through universities and private laboratories in the USA and abroad. However, the vast majority of results from clinically ill dogs are negative for tick-borne diseases, which frustrates veterinarians and dog owners trying to reach a definitive diagnosis and improve treatment options. These panels are based on the detection of previously known DNA sequences of each pathogen, with little room for detecting new organisms. Consequently, the current assays may suffer from "myopia": a self-fulfilling effect that prevents the detection of new or emerging organisms. Using an innovative approach, the investigators will employ next-generation sequencing (NGS) to overcome the limitations of current diagnostic technology. With NGS, the investigators can generate millions of individual gene sequencing reads from each clinical sample, allowing for the identification and characterization of multiple organisms from a single sample. Testing samples from dogs naturally exposed to tick-borne diseases, NGS will detect not only new organisms but also characterize genetic differences among known organisms. The resulting dataset of a large number of DNA sequences of known tick-borne organisms and previously undetected organisms in naturally-infected dogs will support the development of diagnostic tools to simultaneously advance canine and human health.

Report to Grant Sponsor from Investigator:

Dogs from any breed, age or gender can be infected with microbes transmitted by ticks or fleas. These diseases can cause devastating effects and even death not only to dogs but also to humans. Ticks are present everywhere in the US, and they bring the risk of transmitting the microbes to dogs and humans. It is still very difficult to diagnose these conditions, and approximately 95% of suspected dog cases are negative when we use current diagnostic technology. One of the biggest limiting factors for the development of better diagnostic tools is the insufficient funding opportunities for large-scale projects. The long-term goal of our research team is to expand the current diagnostic tools to include a larger spectrum of potentially hazardous microorganisms. Our innovative approach is based on four pillars: (1) large-scale DNA sequencing to identify known and potentially new organisms present in blood of dogs naturally exposed to vector-borne diseases; (2) increase in sensitivity and specificity of large-scale sequencing by targeting major families of potentially hazardous organisms, (3) advanced bioinformatic analysis of millions of DNA sequences from a large number of dogs suspected of infection; and (4) comprehensive quality-control measures in order to support and validate the impact of our results. At this point, we have completed the Specific Aim #1 by performing Universal 16S-NGS on >500 canine samples previously tested by a conventional PCR panel and comparing the results from both techniques. We found high sensitivity rates on the comparison between Universal 16S-NGS and PCR panel for some pathogens. We were also able to detect a known pathogen in approximately one of every five samples previously reported as negative by the conventional PCR panel. We also genetically characterized potential novel strains or species of pathogens. We have now advanced our progress towards Specific Aim #2, which is based on the improvement of the NGS platform for better detection of pathogens. We have expanded the sensitivity of the NGS platform by designing and validating family-level primers for the Anaplasmataceae, Bartonellaceae and Mycoplasmataceae families, as well as for the 18S rRNA gene for the detection of protozoans such as Babesia spp. Our bioinformatics pipeline has proven to be ready to quickly analyze the raw data coming from our large-scale DNA sequencing effort. Finally, we believe we already identified key elements to improve the use of this new technology in veterinary diagnostics. Our results will probably become a paradigm shift in the detection and identification of the cause of vector-borne diseases in dogs, by unveiling thousands of novel potentially hazardous microorganisms. Our data will serve as the new foundation for the implementation and expansion of novel diagnostic methods, and will ultimately support early diagnosis
